## Implied Volatility

Option traders can never fully understand the dynamics behind pricing of stock options and stock option price movements without understanding what volatility and implied volatility are. Volatility can be calculated mathematically to arrive at an expectation of the amount of volatility in the underlying asset or market implied by current price data, hence the development of Implied Volatility. Implied volatility is the second most important price determinant of stock options other than the price of the stock itself.

Mathematically, the factors that affect implied volatility are the exercise price, the riskless rate of return, maturity date and the price of the option. These factors are taken into consideration in several option pricing models, including the Black-Scholes Option Pricing Model. Implied volatility is also the only variable that goes into a mathematical option pricing model.

|  TOS-<br>REQ-4303 |  |
|---|--|

### Implied Volatility Formula

This formula allows to work out the implied volatility that has already been factored into the price of an option.

$$x_{i+1} = x_i - \frac{y_i - p}{v_i}$$

until  $\left| \frac{x_{i+1} - x_i}{x_{i+1}} \right| \leq \varepsilon$  at which point  $x_i = \text{IVOL}$

Where:

$x_i$  = Volatility

$v_i$  = option's Vega at theoretical value  $y_i$

$y_i$  = option's theoretical value at volatility  $x_i$

$p$  = option price

1 item found 

## Theoretical Price

This is a theoretical price of the option, which is used to analyze dependency of the option price on the following factors: changes in stock price, volatility. Option price expectations are calculated for selected expiration date.

TOS uses Bjerksund and Stensland option pricing model.

More information is available here:

[http://www.global-derivatives.com/index2.php?option=com\\_content&do\\_pdf=1&id=14](http://www.global-derivatives.com/index2.php?option=com_content&do_pdf=1&id=14)

| ID | Title / Description |

 TOS-  
REQ-4304

## Theoretical Price Formula

The Bjerksund-Stensland approximation assumes that the exercise is initiated to a corresponding 'flat' boundary, making use of a trigger price. This approximation is computational inexpensive and the method is fast.

For call options:

$$C = \alpha S^{\beta} - \alpha \phi(S, T, \beta, I, I) + \phi(S, T, 1, I, I) - \phi(S, T, 1, X, I) - X \phi(S, T, 0, I, I) + X \phi(S, T, 0, X, I)$$

Where:

$$\alpha = (I - X)I^{-\beta}$$

$$\beta = \left(0.5 - \frac{r-D}{\sigma^2}\right) + \sqrt{\left(\frac{r-D}{\sigma^2} - 0.5\right)^2 + 2\left(\frac{r}{\sigma^2}\right)}$$

$$\phi(S,T,\gamma,H,I) = e^{\lambda} S^{\gamma} \left[ N(d) - \left(\frac{I}{S}\right)^{\kappa} N\left(d - \frac{2\ln(I/S)}{\sigma\sqrt{T}}\right) \right]$$

$$\lambda = \left[ \gamma(r-D) - r + 0.5\gamma(\gamma-1)\sigma^2 \right] T$$

$$d = -\frac{\ln(S/H) + (r-D + (\gamma-0.5)\sigma^2)T}{\sigma\sqrt{T}}$$

$$\kappa = \frac{2(r-D)}{\sigma^2} + (2\gamma-1)$$

$$I = B_0 + (B_{\infty} - B_0)(1 - e^f)$$

$$f = -(T(r-D) + 2\sigma\sqrt{T})\left(\frac{B_0}{B_{\infty} - B_0}\right)$$

$$B_{\infty} = \frac{\beta}{\beta-1} X$$

$$B_0 = \max\left(X, \left(\frac{r}{D}\right)X\right)$$

For put options:

$$P(S,X,T,r,r-D,\sigma) = C(X,S,T,D,D-r,\sigma)$$

## Covered Return

The calculation of Covered return is based on the extrinsic value of the option, the price of the stock, and time to expiration. The reason we use extrinsic value in the calculation is that if you sell an in-the-money call, you would get a large credit because the call price is large. But most of that price is intrinsic value, which you wouldn't capture because you are offsetting that intrinsic amount with the stock trade. Using the extrinsic value lets you compare the return for out-of-the-money and in-the-money options. The highest covered returns are for the at-the-money options because extrinsic value is highest there.

Specifically, the calculation takes the extrinsic value, divides it by the price of the stock, multiplies it by 365 and divides it by the days to expiration.

ID

Title / Description

 TOS-  
REQ-4305

## Covered Return Formula

Covered Return is calculated by the following formula:

$$\text{Covered Return} = (\text{Extrinsic/Mark}) * (365/\text{Days-till-expiration})$$

Where:

Extrinsic - extrinsic value for selected option

Mark - Mark price of underlying stock

Days-till-expiration - quantity of days until selected option expiration date

1 item found 

## Extrinsic

Extrinsic Value, or sometimes known as the Premium Value or Time Value, of an option is the part of the price that is determined by factors other than the price of the underlying stock. This is what you are paying the seller of the option for the risk that the seller is undertaking for selling you the option contract. This "risk money" you are paying the seller is justified and determined by 4 main factors : Time to expiration, Interest Rates, Volatility and Dividends payable.

| ID  | Title / Description      |
|---|--------------------------|
|  TOS-REQ-4306 | <b>Extrinsic Formula</b> |

Extrinsic is calculated by the following formula:

**Extrinsic Value Of Put Option = Put Option Price - Intrinsic Value Of Put Option**

**Extrinsic Value Of Call Option = Call Option Price - Intrinsic Value Of Call Option**

Where:

Extrinsic - extrinsic value for selected option

OptionPrice - Mark price of underlying stock

Days-till-expiration - quantity of days until selected option expiration date

1 item found 

## Intrinsic

Intrinsic value of options is the value of its underlying stock that is built into the price of the option. In fact, options traders buy stock options for the sake of those options gaining intrinsic value ( Long Call or Long Put options trading strategy).

When you buy call options, you do so because you want to to profit when the stock goes up. When the stock moves higher and higher, more and more of the stock's value gets built into the price of the option in the form of intrinsic value.

| ID  | Title / Description      |
|---|--------------------------|
|  TOS-REQ-4307 | <b>Intrinsic Formula</b> |

Intrinsic is calculated by the following formula:

**Intrinsic Value Of Put Option = Strike Option Price - Last Price Of Put Option**

**Intrinsic Value Of Call Option = Last Price of Call Option - Strike Option Price**

1 item found 

## Mark Price for Options

Mark price of option is the average between option Bid and Ask price.

| ID  | Title / Description                   |
|---|---------------------------------------|
|  TOS-REQ-4308 | <b>Mark Price for Options Formula</b> |

Mark Price for option is calculated by the following formula:

$$\text{Mark Price for Option} = (\text{Option's Bid Price} + \text{Option's Ask Price})/2$$

1 item found 

## Expected Price

ID

Title / Description

TOS-  
REQ-4309

### Expected Price

Each spread has its own price which depends on current spread BID/ASK values:

$$SP = \text{SIGNUM} * (\text{ASK} - \text{BID}) / (2 * \text{LEGS}) + M$$

Where:

SIGNUM = 1 when order has positive quantity

SIGNUM = -1 when order has negative quantity

BID/ASK - bid and ask of the spread

LEGS - number of legs of the spread

M = (BID + ASK) / 2

Each spread has its own DELTA.

Each underlying instrument has its own price, UP.

Each order has Order Price, OP.

Expected Underlying Price (EUP) will be calculated as follows:

$$EUP = UP + (\text{OP} - \text{SP}) / \text{DELTA}$$

1 item found 

## SIZZLE Index

SIZZLE Index computes the sum of the current volumes for all calls and all puts for a single stock or index and compare that sum with an average of the sums of the last 5 trading days. The result is a ratio that is a measure of the relative activity in a stock's options. The higher the ratio, the more active the options are. This is a "live" calculation, with the algorithm calculating a new ratio at fixed intervals throughout the trading day.

ID

Title / Description

TOS-  
REQ-4310

### Sizzle Index

Sizzle Index is calculated by the following formulas:

$$\text{Call Sizzle Index} = C0 * 5 / \text{Sum}(C1 + C2 + C3 + C4 + C5)$$

$$\text{Put Sizzle Index} = P0 * 5 / \text{Sum}(P1 + P2 + P3 + P4 + P5)$$

$$\text{Sizzle Index} = (C0 + P0) * 5 / \text{Sum}(C1 + P1 + C2 + P2 + C3 + P3 + C4 + P4 + C5 + P5)$$

Where:

C0 - sum of volumes of all Call options for current trading day

P0 - sum of volumes of all Put options for current trading day

C1, ..., C5 - sums of volumes of all Call options for last five trading days

P1, ..., P5 - sums of volumes of all Put options for last five trading days

## Put/Call Ratio

Put/Call Ratio is one of the two indicators directly derived from options trading, the other one being the VIX. Put/Call Ratio is used by options traders around the world as a contrarian indicator of market sentiment. As an indicator of market sentiment, Put/Call Ratio tells you when investors are in a bullish or bearish mood. Put/Call Ratio is arrived at by dividing the total amount of put options traded by the total amount of call options traded.

There are 2 main types of Put/Call Ratios: Total Equity Put/Call Ratio, Index Put/Call Ratio.

Equity Put/Call Ratio: There are 2 main types of Equity Put/Call Ratios; Total Equities Put/Call Ratio that measures the put/call ratio of all equities in the market and Individual Equity Put/Call Ratio that measures the put/call ratio of an individual stock. The most authoritative total equities put/call ratio in the United States is the Chicago Board Of Exchange Total Equities Put/Call Ratio. The CBOE Total Equities Put/Call Ratio divides the total volume of equity put options by the total volume of equity call options traded daily and serves as the broadest measure of market sentiment in the equity market. The CBOE total equities put call ratio is also what most options traders are referring to when talking about Put/Call Ratios.

Index Put/Call Ratio: Index Put/Call Ratios, also known as Composite Put/Call Ratios, are put call ratios calculated for component stocks in an index such as the OEX. Index put/call ratios are meant to be contrarian indicators for the underlying index but due to the amount of hedging done by portfolio managers and Market Makers in the index options resulting in a skew towards more put option buying than call option buying, Index Put/Call Options are not generally regarded by the options trading community as indicative of general investor sentiment.

| ID | Title / Description |

|----|---------------------|

## Put/Call Ratio

Put/Call Ratio is calculated by the following formula:

$$\text{Volume Of Put Options} / \text{Volume Of Call Options}$$

1 item found 

## Market Capitalization

Market capitalization/capitalisation (aka market cap) is a value of a company, which is equal to multiplication of issued shares and mark price.

ID Title / Description

## Market Capitalization

Market capitalization is calculated by the following formula:

$$\text{Market Cap} = \text{Last Price} * \text{Shares}$$

1 item found 

## Volatility Index

Calculated value, which forecasts expected volatility of the stock over the next 30 calendar days. For calculation of Volatility Index in the thinkorswim we use VIX (CBOE VOLATILITY INDEX) algorithm. Calculation is based on implied volatilities of the option series which will be expired in the near and next expiration dates.

## FRONT Volatility

Calculated value, which forecasts expected volatility of the stock for the near expiration date. Calculation is based on implied volatilities of the option series which will be expired in the near expiration dates.

ID Title / Description

## FRONT Volatility

FRONT Volatility is calculated by the following formula:

**FRONT Volatility = Implied Volatility** of the options on the selected stock with **near expiration date**.

1 item found 

## BACK Volatility

Calculated value, which forecasts expected volatility of the stock for the next expiration date. Calculation is based on implied volatilities of the option series which will be expired in the next expiration dates.

ID Title / Description

## BACK Volatility

BACK Volatility is calculated by the following formula:

**BACK volatility = Implied Volatility** of the options on the selected stock with **near next expiration date**.

1 item found 

**Volatility Difference**

Calculated value which shows difference between FRONT Volatility and BACK Volatility.

## VWAP (Volume Weighted Average Price)

A trading benchmark used especially in pension plans. VWAP is calculated by adding up the dollars traded for every transaction (price multiplied by number of shares traded) and then dividing by the total shares traded for the day. The theory is that if the price of a buy trade is lower than the VWAP, it is a good trade. The opposite is true if the price is higher than the VWAP.

| ID | Title / Description |
|----|---------------------|
|----|---------------------|

 TOS-  
REQ-4318

### Volume Weighted Average Price (VWAP)

## Strength Meter Indicator

The Strength Meter helps to gauge how a stock is trending. The foundation of the Strength Meter is derived from a stock's three-week trend:

- Stocks moving up 10% or more (during that period) are given a Green or Trending Up rating.

- Stocks moving down 10% or more during that period are given a Red or Trending Down rating.
- Stocks moving less than 9% during that period are given a Yellow or Range Bound rating.

## Historical Volatility Formula

Historical Volatility is the realized volatility of a financial instrument over a given time period. Generally, this measure is calculated by determining the average deviation from the average price of a financial instrument in the given time period. Standard deviation is the most common but not the only way to calculate historical volatility.

Historical Volatility is also known as "statistical volatility".

Historical Volatility is often used in all types of risk valuations. Stocks with a high historical volatility usually require a higher risk tolerance.

| ID   | Title / Description                  | Status  | Time Point                  |
|--|--------------------------------------|---|-----------------------------|
|  TOS-REQ-15172 | <b>Historical Volatility Formula</b> |  QA Review | Condor Release (2011-12-17) |

System shall calculate **Historical Volatility** for non-optionable instrument on the period of 20 days by the following formula:

$$HV = StDev (\ln(close/close [1] ), 20) * \sqrt{trading\_days\_in\_a\_year},$$

Where:

**trading\_days\_in\_a\_year** is often taken as **252**.

## Appendix A: Terminology/Glossary/Definitions list

**Implied Volatility** - A measure of the volatility of the underlying stock, it is determined by using prices currently existing in the market at the time, rather than using historical data on the price changes of the underlying stock.

**Theoretical Price** - The value generated by a mathematical model given certain prior assumptions about the terms of the option, the characteristics of the underlying contract, and prevailing interest rates.

**Covered Return** - The value gives you an annualized percent, return on buying stock and selling a call, or selling stock and selling a put.

**Extrinsic** - The difference between an option's price and the intrinsic value.

**Intrinsic** - For call options, this is the difference between the underlying stock's price and the strike price. For put options, it is the difference between the strike price and the underlying stock's price. In the case of both puts and calls, if the respective difference value is negative, the intrinsic value is given as zero.

**YIELD** - The income return on an investment.

**Put Call Ratio** - The ratio of the number of open put options against the number of open call options. The higher the resulting number, the more put options are bought or shorted on the underlying asset.
